

Writing Device Support

Andrew Johnson
AES Software Services Group

Writing Device Support - Scope

- An overview of the concepts associated with writing EPICS Device Support routines.
- Examples show the “stone knives and bearskins” approach.
- The ASYN package provides a framework which makes writing device support much easier.
 - The concepts presented here still apply.

Writing Device Support - Outline

- What is 'Device Support'?
- The .dbd file entry
- The driver DSET
- Device addresses
- Support routines
- Using interrupts
- Asynchronous input/output
- Callbacks

What is 'Device Support'?

- Interface between record and hardware
- A set of routines for record support to call
 - The record type determines the required set of routines
 - These routines have full read/write access to any record field
- Determines synchronous/asynchronous nature of record
- Performs record I/O
 - Provides interrupt handling mechanism

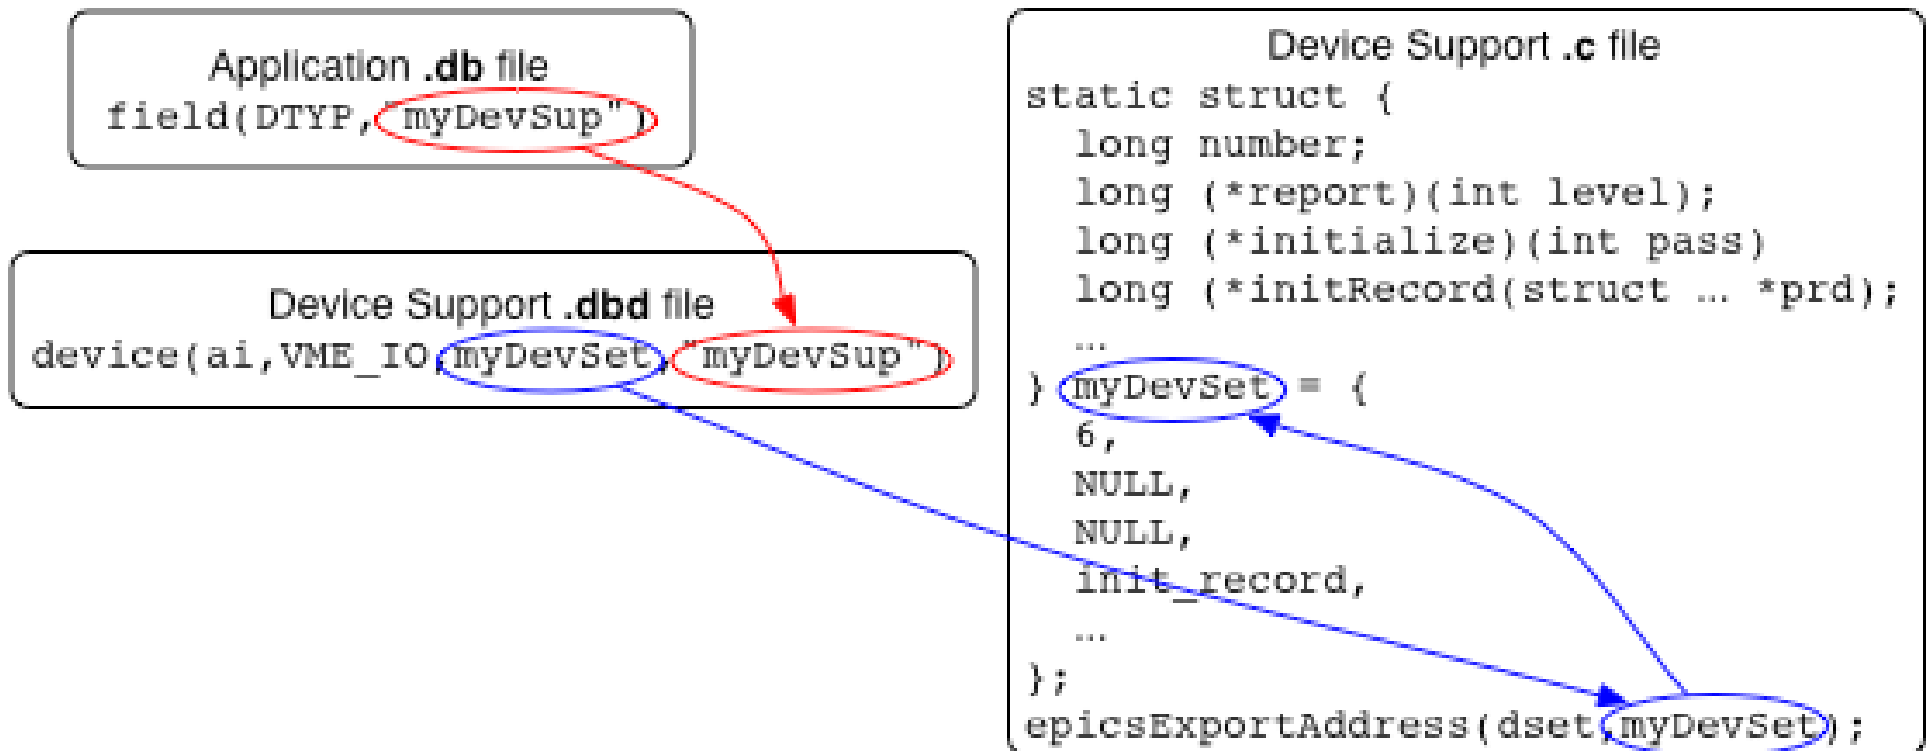

Why use device support?

- Could instead make a different record type for each hardware interface, with fields to allow full control over the provided facilities.
- A separate device support level provides several advantages:
 - Users need not learn a new record type for each type of device
 - Increases modularity
 - I/O hardware changes are less disruptive
 - Device support is simpler than record support
 - Hardware interface code is isolated from record API
- Custom records are available if really needed.
 - By which I mean “really, really, really needed!”
 - Existing record types are sufficient for most applications.

How does a record find its device support?

Through .dbd file 'device' statements:

The .dbd file entry

- The IOC discovers device support from entries in .dbd files

```
device( recType , addrType , dsetName , "dtypeName" )
```

- *addrType* is one of

AB_IO	BITBUS_IO	CAMAC_IO	GPIB_IO
INST_IO	RF_IO	VME_IO	VXI_IO

- *dsetName* is the name of the C Device Support Entry Table (DSET)

- By convention name indicates record and hardware type:

```
device(ai, GPIB_IO, devAidg535, "dg535")
```

```
device(bi, VME_IO, devBiXy240, "XYCOM-240")
```

The DSET

- A C structure containing pointers to functions
- Content dependent upon record type
- Each device support layer defines a DSET with pointers to its own functions
- A DSET structure declaration looks like:

```
struct dset {  
    long number;  
    long (*report)(int level);  
    long (*initialize)(int pass);  
    long (*initRecord)(struct ... *precord);  
    long (*getIoIntInfo)(...);  
    ... read/write and other routines as required  
};
```

- **number** specifies number of pointers (often 5 or 6)
- A NULL is given when an optional routine is not implemented
- DSET structures and functions are usually declared **static**

The DSET - initialize

```
long initialize(int pass);
```

- Initializes the device support layer
- Optional routine, not always needed
- Used for one-time startup operations:
 - Start background tasks
 - Create shared tables
- Called twice by ioclnit()
 - `pass=0` – Before any record initialization
 - Doesn't usually access hardware since device address information is not yet known
 - `pass=1` – After all record initialization
 - Can be used as a final startup step. All device address information is now known

The DSET - `initRecord`

```
long initRecord(struct ... *precord);
```

- Called by `ioclnit()` once for each record with matching DTYP
- Optional routine, but usually supplied
- Routines often
 - Validate the INP or OUTP field
 - Verify that addressed hardware is present
 - Allocate device-specific storage for the record
 - Each record contains a `void *dpvt` pointer for this purpose
 - Program device registers
 - Set record-specific fields needed for conversion to/from engineering units

The DSET - read/write

```
long read(struct ... *precord);  
long write(struct ... *precord);
```

- Called when record is processed
- Perform (or initiate) the I/O operation:
 - Synchronous input
 - Copy value from hardware into `precord->rval`
 - Return 0 (to indicate success)
 - Synchronous output
 - Copy value from `precord->rval` to hardware
 - Return 0 (to indicate success)

The DSET - initRecord - Device Addresses

- Device support .dbd entry was

```
device(recType, addrType, dset, "name")
```

- *addrType* specifies the type to use for the address link, e.g.

```
device(bo, VME_IO, devBoXy240, "Xycom XY240")
```

sets pbo->out:

- pbo->out.type = VME_IO
- Device support uses pbo->out.value.vmeio which is a

```
struct vmeio {  
    short card;  
    short signal;  
    char *parm;  
};
```

- IOC Application Developer's Guide describes all types

A simple example (vxWorks or RTEMS)

```
#include <recGbl.h>
#include <devSup.h>
#include <devLib.h>
#include <biRecord.h>
#include <epicsExport.h>
static long initRecord(struct biRecord *prec){
    char *pbyte, dummy;
    if ((prec->inp.type != VME_IO) ||
        (prec->inp.value.vmeio.signal < 0) || (prec->inp.value.vmeio.signal > 7)) {
        recGblRecordError(S_dev_badInpType, (void *)prec, "devBiFirst: Bad INP");
        return -1;
    }
    if (devRegisterAddress("devBiFirst", atVMEA16, prec->inp.value.vmeio.card, 0x1,
                          &pbyte) != 0) {
        recGblRecordError(S_dev_badCard, (void *)prec, "devBiFirst: Bad VME
address");
        return -1;
    }
    if (devReadProbe(1, pbyte, &dummy) < 0) {
        recGblRecordError(S_dev_badCard, (void *)prec, "devBiFirst: Nothing
there!");
        return -1;
    }
    prec->dpvt = pbyte;
    prec->mask = 1 << prec->inp.value.vmeio.signal;
    return 0;
}
```

A simple example (vxWorks or RTEMS)

```
static long read(struct biRecord *prec)
{
    volatile char *pbyte = (volatile char *)prec->dpvt;

    prec->rval = *pbyte;
    return 0;
}

static struct {
    long number;
    long (*report)(int);
    long (*initialize)(int);
    long (*initRecord)(struct biRecord *);
    long (*getIoIntInfo)();
    long (*read)(struct biRecord *);
} devBiFirst = {
    5, NULL, NULL, initRecord, NULL, read
};
epicsExportAddress(dset, devBiFirst);
```

The DSET - report

```
long report(int level);
```

- Called by `dbior` shell command
- Prints information about current state, hardware status, I/O statistics, etc.
- Amount of output is controlled by the level argument
 - `level=0` – list hardware connected, one device per line
 - `level>0` – provide different type or more detailed information

A simple example - device support .dbd file

The .dbd file for the device support routines shown on the preceding pages might be

```
device(bi, VME_IO, devBiFirst, "simpleInput")
```

A simple example - application .db file

An application .db file using the device support routines shown on the preceding pages might contain

```
record(bi, "$(P):statusBit")
{
    field(DESC, "Simple example binary input")
    field(DTYP, "simpleInput")
    field(INP, "#C$(C) S$(S)")
}
```

A simple example - application startup script

An application startup script (st.cmd) using the device support routines shown on the preceding pages might contain

```
dbLoadRecords ("db/example.db", "P=test,C=0x1E0,S=0")
```

which would expand the .db file into

```
record(bi, "test:statusBit")
{
    field(DESC, "Simple example binary input")
    field(DTYP, "simpleInput")
    field(INP, "#C0x1E0 S0")
}
```

Useful facilities

- ANSI C routines (EPICS headers fill in vendor holes)
 - epicsStdio.h – printf, scanf, epicsSnprintf
 - epicsString.h – strcpy, memcpy, epicsStrDup
 - epicsStdlib.h – getenv, abs, epicsScanDouble
- OS-independent hardware access (devLib.h)
 - Bus address Local address conversion
 - Interrupt control
 - Bus probing
- EPICS routines
 - epicsEvent.h – process synchronization semaphore
 - epicsMutex.h – mutual-exclusion semaphore
 - epicsThread.h – multithreading support
 - recGbl.h – record error and alarm reporting

Device Interrupts

- vxWorks/RTEMS interrupt handlers can be written in C
- VME interrupts have two parameters
 - Interrupt level (1-7, but don't use level 7 on M68k) – often set with on-board jumpers or DIP switches
 - Interrupt vector (0-255, <64 reserved on MC680x0) – often set by writing to an on-board register
- OS initialization takes two calls
 1. Connect interrupt handler to vector

```
devConnectInterruptVME(unsigned vectorNumber,  
                        void (*pFunction)(void *),void *parameter);
```
 1. Enable interrupt from VME to CPU

```
devEnableInterruptLevelVME (unsigned level);
```

I/O interrupt record processing

- Record is processed when hardware interrupt occurs
- Granularity depends on device support and hardware
 - Interrupt per-channel vs. interrupt per-card
- `#include <dbScan.h>` to get additional declarations
- Call `scanIoInit` once for each interrupt source to initialize a local value:

```
scanIoInit (&ioscanpvt);
```
- DSET must provide a `getIoIntInfo` routine to specify the interrupt source associated with a record – a single interrupt source can be associated with more than one record
- Interrupt handler calls `scanIoRequest` with the `'ioscanpvt'` value for that source – this is one of the very few routines which may be called from an interrupt handler

The DSET - getIoIntInfo

```
long getIoIntInfo(int cmd, struct ... *precord,  
                  IOSCANPVT *ppvt);
```

- Set ***ppvt** to the value of the **IOSCANPVT** variable for the interrupt source to be associated with this record
- You may call **scanIoInit** to initialize the **IOSCANPVT** variable if you haven't done so already
- Return 0 to indicate success or non-zero to indicate failure – in which case the record **SCAN** field will be set to **Passive**
- Routine is called with
 - (cmd=0) when record is set to SCAN=I/O Intr
 - (cmd=1) when record SCAN field is set to any other value

The DSET - specialLinconv

```
long specialLinconv(struct ... *precord, int after);
```

- Analog input (ai) and output (ao) record DSETs include this sixth routine
- Called just before (**after=0**) and just after (**after=1**) the value of the **LINR**, **EGUL** or **EGUF** fields changes
- “Before” usually does nothing
- “After” recalculates **ESLO** from **EGUL/EGUF** and the hardware range if **LINR** is **LINEAR**. Doesn’t change **ESLO** if **LINR** is **SLOPE**.
- If record **LINR** field is **Linear** ai record processing will compute **val** as
$$\text{val} = ((\text{rval} + \text{roff}) * \text{aslo} + \text{aoff}) * \text{eslo} + \text{eoff}$$
Ao record processing is similar, but in reverse

Asynchronous I/O

- Device support must not wait for slow I/O
- Hardware read/write operations which take “a long time” to complete must use asynchronous record processing
 - $T_{I/O} \geq 100 \mu s$ – definitely “a long time”
 - $T_{I/O} \leq 10 \mu s$ – definitely “not a long time”
 - $10 \mu s < T_{I/O} < 100 \mu s$ – ???
- If device does not provide a completion interrupt a “worker” thread can be created to perform the I/O
 - this technique is used for Ethernet-attached devices

Asynchronous I/O - read/write operation

- Check value of `precord->pact` and if zero:
 - Set `precord->pact` to 1
 - Start the I/O operation
 - write hardware or send message to worker thread
 - Return 0
- When operation completes run the following code from a thread (i.e. NOT from an interrupt handler)

```
struct rset *prset = (struct rset *)precord->rset;
dbScanLock(precord);
(*prset->process)(precord);
dbScanUnlock(precord);
```
- The record's process routine will call the device support read/write routine - with `precord->pact=1`
 - Complete the I/O, set `rval`, etc.

Asynchronous I/O - callbacks

- An interrupt handler must not call a record's process routine directly
- Use the callback system (`callback.h`) to do this
- Declare a callback variable

```
CALLBACK myCallback;
```
- Issue the following from the interrupt handler

```
callbackRequestProcessCallback(&myCallBack,  
    priorityLow, precord);
```
- This queues a request to a callback handler thread which will perform the lock/process/unlock operations shown on the previous page
- There are three callback handler threads
 - With priorities Low, Medium and High

Extended device support

- Device support has been extended to include runtime changes of addresses in IN/OUT fields
- Beginnings of support for failover
- See application developer's guide for details

Asynchronous I/O - ASYN

- Asyn should be your first consideration for new device support
- It provides a powerful, flexible framework for writing device support for
 - Message-based asynchronous devices
 - Register-based synchronous devices
- Will be completely described in subsequent lectures
