Channel Access Client Programming

Andrew Johnson — AES/SSG, Argonne

Includes material from:
- Ken Evans, Argonne
- Kay Kasemir, ORNL
- Matt Newville, CARS UChicago
Task: Write a Channel Access client

- Many possible approaches and choices of language
- Assuming that you need more than you can do with
  - MEDM/EDM/CaQtDm/EpicsQt display manager
  - CSS/Boy with its rules and scripts
- These are commonly used options
  - Shell or Perl script that calls the caget/caput/camonitor programs
  - Python program with PyEpics or EPICS Cothread bindings
  - Matlab/Octave/Scilab with MCA or LabCA bindings
  - State Notation Language (SNL) program with the Sequencer
  - Perl program with CA bindings
  - C++ program with EPICS Qt bindings
  - Java program calling CAJ (pure Java) or JCA (JNI)
  - C/C++ program calling CA library
SNL programs speak CA natively

- This piece of SNL handles all the connection management and data type handling:
  - double value;
    assign value to "fred";
    monitor value;

- Extend into a basic 'camonitor':
  - evflag changed;
    sync value changed;

```c
ss monitor_pv
{
  state check
  {
    when (efTestAndClear(changed))
    {
      printf("Value is now %g\n", value);
    } state check
  }
}
```
Quick Hacks, Simple Scripts

- In many cases, scripts written in bash/perl/python/php can just invoke the command-line ‘caget’ and ‘caput’ programs
- Useful for reading/writing one or two PV values, not for subscribing to value updates
- Quiz: Why would a loop that continually invokes ‘caget’ or ‘caput’ be bad?

- CA Client library bindings are available for Perl, Python & PHP
  - Perl bindings are included in EPICS Base (not available on MS Windows)
  - Several different Python bindings are available
- Much better to use these for long-running scripts
Simple Script Example

#!/bin/env perl -w

# caget: Get the current value of a PV
# Argument: PV name
# Result: PV value
sub caget {
    my ($pv) = @_;  
    open(my $F, "-|", "caget -t $pv") or die "Cannot run 'caget'\n";
    $result = <$F>;
    close $F;
    chomp $result;
    return $result;
}

# Do stuff with PVs
my $fred = caget("fred");
my $jane = caget("jane");
my $sum = $fred + $jane;
printf("Sum: %g\n", $sum);
Channel Access for Python

- Two CA client bindings are currently recommended
  - PyEpics: Matt Newville, CARS & University of Chicago
  - Cothread: Michael Abbott, Diamond

- Differences not huge, evaluate both?
  - PyEpics provides a higher-level Device API, wxPython widgets, more extensive documentation
  - Cothread provides a cooperative multi-threading library

- Websites for both bindings are linked from the EPICS Extensions page

- This section of lecture covers PyEpics
  - Procedural interface (caget, caput, cainfo, camonitor)
  - PV Objects API
Procedural Interface: `caget()`, `caput()`

- Easy-to-use interface, similar to the basic command-line tools

```python
>>> from epics import caget, caput

>>> m1 = caget('XXX:m1.VAL')
>>> print m1
-1.2001

>>> caput('XXX:m1.VAL', 0)

>>> caput('XXX:m1.VAL', 2.30, wait=True)

>>> print caget('XXX:m1.DIR')
1

>>> print caget('XXX:m1.DIR', as_string=True)
'Pos'
```

caput(pvname, wait=True) waits until processing completes. Also support a timeout option (wait no longer than specified time)

caget(pvname, as string=True) returns the String Representation of value (Enum State Name, formatted floating point numbers, . . . )

Many other options available that control exactly what these functions will do, see documentation
Procedural Interface: cainfo(), camonitor()

- cainfo() also fetches status information and metadata for the channel:

  >>> cainfo('XXX.m1.VAL')
  == XXX:m1.VAL (double) ==
  value      = 2.3
  char_value = 2.3000
  count      = 1
  units      = mm
  precision  = 4
  host       = xxx.aps.anl.gov:5064
  access     = read/write
  status     = 1
  severity   = 0
  timestamp  = 1265996455.417 (2010-Feb-12 11:40:55.417)
  upper_ctrl_limit    = 200.0
  lower_ctrl_limit    = -200.0
  upper_disp_limit    = 200.0
  lower_disp_limit    = -200.0
  upper_alarm_limit   = 0.0
  lower_alarm_limit   = 0.0
  upper_warning_limit = 0.0
  lower_warning       = 0.0
  PV is monitored internally
  no user callbacks defined.

- camonitor() monitors the PV, printing a message for every value change until camonitor_clear() is called:

  >>> camonitor('DMM:Ch2.VAL')
  DMM:Ch2.VAL 2010-02-12 12:12:59.502945 -183.9741
  DMM:Ch2.VAL 2010-02-12 12:13:00.500758 -183.8320
  DMM:Ch2.VAL 2010-02-12 12:13:01.501570 -183.9309
  DMM:Ch2.VAL 2010-02-12 12:13:02.502382 -183.9285
  ...

  >>> camonitor_clear('XXX:DMM1Ch2_calc.VAL')

- Can provide a callback function to change the formatting or do something other than print the value each time

- PVs are cached internally, so searches are not repeated for subsequent calls to these library routines
PV Objects: Easy to use, rich features

```python
>>> from epics import PV
>>> pv1 = PV('XXX:m1.VAL')
>>> print pv1.count, pv1.type
(1, 'double')

>>> print pv1.get()
-2.3456700000000001

>>> pv1.put(2.0)

>>> pv1.value = 3.0  # = pv1.put(3.0)
>>> pv1.value = 3.0  # = pv1.get()
3.0

>>> print pv.get(as_string=True)
'3.0000'

>>> # user defined callback
>>> def onChange(pvname=None, value=None, **kws):
...     fmt = 'New Value for %s value=%s\n'
...     print fmt % (pvname, str(value))

>>> # subscribe for changes
>>> pv1.add_callback(onChange)

>>> while True:
...     time.sleep(0.001)
```

- Automatic connection management
- Attributes for many properties (count, type, host, limits... etc)
- Use `get()` / `put()` methods or the `.value` attribute
- Use `as_string=True` argument for Enum labels or record-selected floating point display precision
- `put()` can wait for completion, or call a function when done
- Callback functions can be given to the PV() constructor for value and connection status changes
- Can have multiple value callback functions
User-Supplied Callbacks for PV Changes

```python
import epics
import time

def onChange(pvname=None, value=None, char_value=None, **kws):
    '''callback for PV value changes'''
    print 'PV Changed! ', pvname, \
    char_value, time.ctime()

mypv = epics.PV(pvname)

# Add the callback
mypv.add_callback(onChange)

print 'Now watch for changes for a minute'

t0 = time.time()
while time.time() - t0 < 60.0:
    time.sleep(1.e-3)

mypv.clear_callbacks()
print 'Done.'
```

- **User-defined callback function must take keyword arguments**, e.g.
  - `pvname` Name of PV
  - `value` New value
  - `char_value` String representation of value
  - `count` Element count
  - `ftype` Field type (DBR integer)
  - `type` Python data type
  - `status` CA status, 1 = OK
  - `precision` PV precision
  - `**kws` Many more CTRL values for limits, units etc.

- **User-defined put- and connection-callback functions must expect similar arguments**
Waveform / Array Data and Long Strings

- If numpy is installed it will be used; if not get() will return a Python list

```python
>>> p1vals = numpy.linspace(3, 4, 101)
```

```python
>>> scan_p1 = PV('XXX:scan1.P1PA')
>>> scan_p1.put(p1vals)
```

```python
>>> print scan_p1.get()[:101]
[3. , 3.01, 3.02, ..., 3.99, 3.99, 4.]
```

- CA only carries strings up to 40 chars
- Arrays of characters must be used for longer strings. An `as_string=True` argument will convert ASCII data

```python
>>> folder = PV('XXX:directory')
>>> print folder
<PV 'XXX:directory', count=21/128,
  type=char, access=read/write>
```

```python
>>> folder.get()
array([ 84, 58, 92, 120, 97, 115, 95, 117,
       115, 101, 114, 92, 77, 97, 114, 99,
       104, 50, 48, 49, 48])
```

```python
>>> folder.get(as_string=True)
'T:\xas user\March2010'
```

```python
>>> folder.put('T:\xas user\April2010')
```
PyEpics Internal Design Choices

- The module hides many Channel Access details that most users won’t need
  - Most of these settings can be changed if necessary
- It also provides a higher-level Device API (not covered here)
- Runs in libCa’s preemptive multi-threading mode, user code never has to call functions like `ca_pend_event()` or `ca_pend_io()`

- Sets `EPICS_CA_MAX_ARRAY_BYTES` to 16777216 (16Mb) unless already set
- Usually registers internal Connection and Event handlers. User-defined callback functions are then called by the internal handler
- Event Callbacks are used internally except for large arrays, as defined by `ca.AUTOMONITOR_LENGTH` (default = 16K)
- Event subscriptions use mask of `(EVENT | LOG | ALARM)` by default
Channel Access for Perl, C and C++

- The Channel Access client library comes with EPICS base and is the basis for most of the other language bindings
  - Internally written in C++ but API is pure C
  - Main exception: Pure Java library ‘CAJ’

- Documentation:
  - *CA - Perl 5 interface to EPICS Channel Access* by Andrew Johnson
    - In <base>/html, or from the EPICS web site

- This section covers
  - Fundamental API concepts using Perl examples
  - Some brief examples in C
  - How to instantiate a template with some example C programs
CA Client APIs for Perl, C and C++

- Why teach the Perl API before C?
  - Higher level language than C, no pointers needed
  - Learn the main principles and library calls with less code
  - Complete Perl programs can fit on one slide

- The Perl 5 API is a thin wrapper around the C library
  - Built with Base on most Unix-like workstation platforms (not Windows)
  - Provides the same interface model that C code uses
  - Unless you’re interfacing to specific libraries or need very high performance, Perl scripts may be sufficient for most tasks

- Other APIs like Python and Java are less like the C library
  - Good for writing client programs in Python/Java, but not for learning the C library
Search and Connect to a PV

use lib '/path/to/base/lib/perl';
use CA;

my $chan = CA->new($ARGV[0]);
CA->pend_io(1);

printf "PV: %s\n", $chan->name;
printf "  State:         %s\n", $chan->state;
printf "  Host:          %s\n", $chan->host_name;
my @access = ('no ', '');
printf "  Access rights: %sread, %swrite\n",
       $access[$chan->read_access], $access[$chan->write_access];
printf "  Data type:     %s\n", $chan->field_type;
printf "  Element count: %d\n", $chan->element_count;

- This is the basic cainfo program in Perl (without error checking)
Get and Put a PV

use lib '/path/to/base/lib/perl';
use CA;

my $chan = CA->new($ARGV[0]);
CA->pend_io(1);

$chan->get;
CA->pend_io(1);
printf "Old Value: %s\n", $chan->value;

$chan->put($ARGV[1]);
CA->pend_io(1);

$chan->get;
CA->pend_io(1);
printf "New Value: %s\n", $chan->value;

- This is the basic caput program in Perl (without error checking)
Monitor a PV

use lib '/path/to/base/lib/perl';
use CA;

my $chan = CA->new($ARGV[0]);
CA->pend_io(1);

$chan->create_subscription('v', \&val_callback);
CA->pend_event(0);

sub val_callback {
    my ($chan, $status, $data) = @_;
    if (!$status) {
        printf "PV: %s\n", $chan->name;
        printf " Value: %s\n", $data;
    }
}

- This is a basic camonitor program in Perl (without error checking)
Error Checking

- What happens if the PV search fails, e.g. the IOC isn't running, or it's busy and takes longer than 1 second to reply?
  - CA->pend_io(1) times out
  - CA library throws a Perl exception (die)
  - Program exits after printing:
    - ECA_TIMEOUT - User specified timeout on IO operation expired at test.pl line 5.

- We can trap the Perl exception using
  - eval {CA->pend_io(1)};
    if ($@ =~ m/^ECA_TIMEOUT/) { ... }

- How can we write code that can recover from failed searches and continue doing useful work?
Event-driven Programming

- First seen when setting up the CA monitor:
  - `$chan->create_subscription('v', \&callback);
    CA->pend_event(0);`
  - The CA library executes our callback subroutine whenever the server provides a new data value for this channel
  - The `CA->pend_event()` routine must be running for the library to execute callback routines
    - The Perl CA library is single threaded
    - Multi-threaded C programs can avoid this requirement

- Most CA functionality can be event-driven
Event-driven PV Search and Connect

use lib '/path/to/base/lib/perl';
use CA;

my @chans = map {CA->new($_, \&conn_callback)} @ARGV;
CA->pend_event(0);

sub conn_callback {
    my ($chan, $up) = @_; 
    printf "PV: %s\n", $chan->name;
    printf " State: %s\n", $chan->state;
    printf " Host: %s\n", $chan->host_name;
    my @access = ('no ', '');
    printf " Access rights: %sread, %swrite\n",
        $access[$chan->read_access], $access[$chan->write_access];
    printf " Data type: %s\n", $chan->field_type;
    printf " Element count: %d\n", $chan->element_count;
}

- The cainfo program using callbacks
Event-driven PV Monitor

```perl
use lib '/path/to/base/lib/perl';
use CA;
my @chans = map {CA->new($_, \&conn_cb)} @ARGV;
CA->pend_event(0);
sub conn_cb {
    my ($ch, $up) = @_;  
    if ($up && ! $monitor{$ch}) {
        $monitor{$ch} = $ch->create_subscription('v', \&val_cb);
    }
}
sub val_cb {
    my ($ch, $status, $data) = @_;  
    if (!$status) {
        printf "PV: %s\n", $ch->name;
        printf "  Value: %s\n", $data;
    }
}
```

- The camonitor program using callbacks
Data Type Requests

- Most data I/O routines handle data type automatically
  - `$chan->get` fetches one element in the channel’s native type
    - Value is returned by `$chan->value`
    - Arrays are not supported, no type request possible
  - `$chan->get_callback(SUB)` fetches all elements in the channel’s native data type
    - Optional TYPE and COUNT arguments to override
  - `$chan->create_subscription(MASK, SUB)` requests all elements in the channel’s native type
    - Optional TYPE and COUNT arguments to override
  - `$chan->put(VALUE)` puts values in the channel’s native type
    - VALUE may be a scalar or an array
  - `$chan->put_callback(SUB, VALUE)` puts values in the channel’s native data type
    - VALUE may be a scalar or an array
Specifying Data Types

- The TYPE argument is a string naming the desired DBR_xxx type
  - See the CA Reference Manual for a list
- The COUNT argument is the integer number of elements

- If you request an array, the callback subroutine’s $data argument becomes an array reference
- If you request a composite type, the callback subroutine’s $data argument becomes a hash reference
  - The hash elements are different according to the type you request
  - See the Perl Library documentation for details
Simple Channel Access calls from C

- Main header file
  - `#include <cadef.h>`
  - This also includes db_access.h, caerr.h and caeventmask.h

- Channels are referred to using as a `chid`, a pointer to an opaque structure
  - `chid fred;`

- Connect to a channel
  - `int status = ca_create_channel("fred", NULL, NULL, 0, &fred);`
  - `SEVCHK(status, "Create channel failed");`
  - `status = ca_pend_io(1.0);`
  - `SEVCHK(status, "Channel connection failed");`

- The `SEVCHK(status, text)` macro is useful for simple programs
  - Aborts with an error message on bad status
What’s in a chid?

- We can get channel information from a connected chid
  
  ```
  const char *ca_state_to_text[4] = {
      "Never connected",
      "Not connected",
      "Connected",
      "Closed"};

  printf("PV: %s\n", ca_name(fred));
  printf("State: %s\n", ca_state_to_text[ca_state(fred)]);
  printf("Host:  %s\n", ca_host_name(fred));
  printf("Read:  %s\n", ca_read_access(fred) ? "Y" : "N");
  printf("Write: %s\n", ca_write_access(fred) ? "Y" : "N");
  printf("Type:  %s\n", dbr_type_to_text(ca_field_type(fred)));
  printf("Count: %s\n", ca_element_count(fred));
  ```

- Tidy up after we’re finished with fred
  
  ```
  SEVCHK(ca_clear_channel(fred), "Clear channel failed");
  ```
Writing to a PV

- Assuming the chid fred is already/still connected
  - ```
  SEVCHK(ca_put(DBR_STRING, fred, "10"), "Put failed");
  ca_flush_io();
  ```

- If fred’s PV can hold an array of doubles
  - ```
  dbr_double_t data[] = {1.0, 2.0, 3.0, 4.0, 5.0};
  SEVCHK(ca_array_put(DBR_DOUBLE, 5, fred, data), "Put failed");
  ca_flush_io();
  ```

- What other data types are available?
  - See the db_access.h file in Base/include
Reading from a PV

- Still assuming fred is connected

```
struct dbr_time_double val;
const char * severity_to_text[4] = {
    "No alarm", "Minor", "Major", "Invalid"};

SEVCHK(ca_get(DBR_TIME_DOUBLE, fred, &val), "Get failed");
SEVCHK(ca_pend_io(1.0), "I/O failed");
printf("PV: %s\n", ca_name(fred));
printf("value: %g\n", val.value);
printf("severity: %s\n", severity_to_text[val.severity]);
printf("status: %hd\n", val.status);
```
Base caClient template

- EPICS Base Includes a makeBaseApp.pl template that builds two basic CA client programs written in C:
  - Run this
    ```
    makeBaseApp.pl -t caClient cacApp
    make
    ```
  - Result
    ```
    bin/linux-x86/caExample <some PV>
    bin/linux-x86/caMonitor <file with PV list>
    ```
  - Then read the sources, compare with the reference manual, and edit/extend to suit your needs
CaClient's caExample.c

- Minimal CA client program
- Fixed timeout, waits until data arrives
- Requests everything as ‘DBR_DOUBLE’
  - ... which results in values of type ‘double’
  - See db_access.h header file for all the DBR_... constants and the resulting C types and structures
  - In addition to the basic DBR_type requests, it is possible to request packaged attributes like DBR_CTRL_type to get \{ value, units, limits, ...\} in one request
Excerpt from db_access.h

/* values returned for each field type

    DBR_DOUBLE      returns a double precision floating point number
    DBR_CTRL_DOUBLE returns a control double structure (dbr_ctrl_double)
*/

/* structure for a control double field */
struct dbr_ctrl_double{
    dbr_short_t     status;                     /* status of value */
    dbr_short_t     severity;                   /* severity of alarm */
    dbr_short_t     precision;                  /* number of decimal places */
    dbr_short_t     RISC_pad0;                  /* RISC alignment */
    char            units[MAX_UNITS_SIZE];      /* units of value */
    dbr_double_t    upper_disp_limit;          /* upper limit of graph */
    dbr_double_t    lower_disp_limit;          /* lower limit of graph */
    dbr_double_t    upper_alarm_limit;
    dbr_double_t    upper_warning_limit;
    dbr_double_t    lower_warning_limit;
    dbr_double_t    lower_alarm_limit;
    dbr_double_t    upper_ctrl_limit;          /* upper control limit */
    dbr_double_t    lower_ctrl_limit;          /* lower control limit */
    dbr_double_t    value;                      /* current value */
};
caClient's caMonitor.c

- Better CA client program
  - Registers callbacks to get notified when connected or disconnected
  - Subscribes to value updates instead of waiting
  - ... but still uses one data type (DBR_STRING) for everything
Java

- There are 2 CA implementations for Java: JCA using JNI, or CAJ in pure Java
  - Only difference is the initialization, both provide the same API
  - Usage is similar to the Perl interface, object-oriented “real programming” as opposed to Matlab, but in the more forgiving Java VM

- A Java CA example can be found at
  - [http://ics-web.sns.orl.gov/kasemir/train_2006/4_2_Java_CAJ.tgz](http://ics-web.sns.orl.gov/kasemir/train_2006/4_2_Java_CAJ.tgz)
Ideal CA client?

- Register and use callbacks for everything
  - Event-driven programming; polling loops or fixed time outs

- On connection, check the channel’s native type
  - Limit the data type conversion burden on the IOC

- Request the matching DBR_CTRL_type once
  - this gets the full channel detail (units, limits, ...)

- Then subscribe to DBR_TIME_type for time+status+value updates
  - Now we always stay informed, yet limit the network traffic
  - Only subscribe once at first connection; the CA library automatically re-activates subscriptions after a disconnect/reconnect

- This is what CSS, EDM, ALH etc. do
  - Quirk: Most don't learn about run-time changes of limits, units, etc.
    - Recent versions of CA support DBE_PROPERTY monitor event type
    - This will solve that issue, once the programs and gateway use it
